THE MENARD PRESSUREMETER : history, equipment, new developments, installation procedures, design rules and methods

By Serge Varaksin,
Vice Chairman TC211
Scientific Advisor

ISSMGE – TC 211

2.1 History

2.2 Concept of pressuremeter

2.3 New developments

2.4 Installation procedures

2.4 Design rules and methods

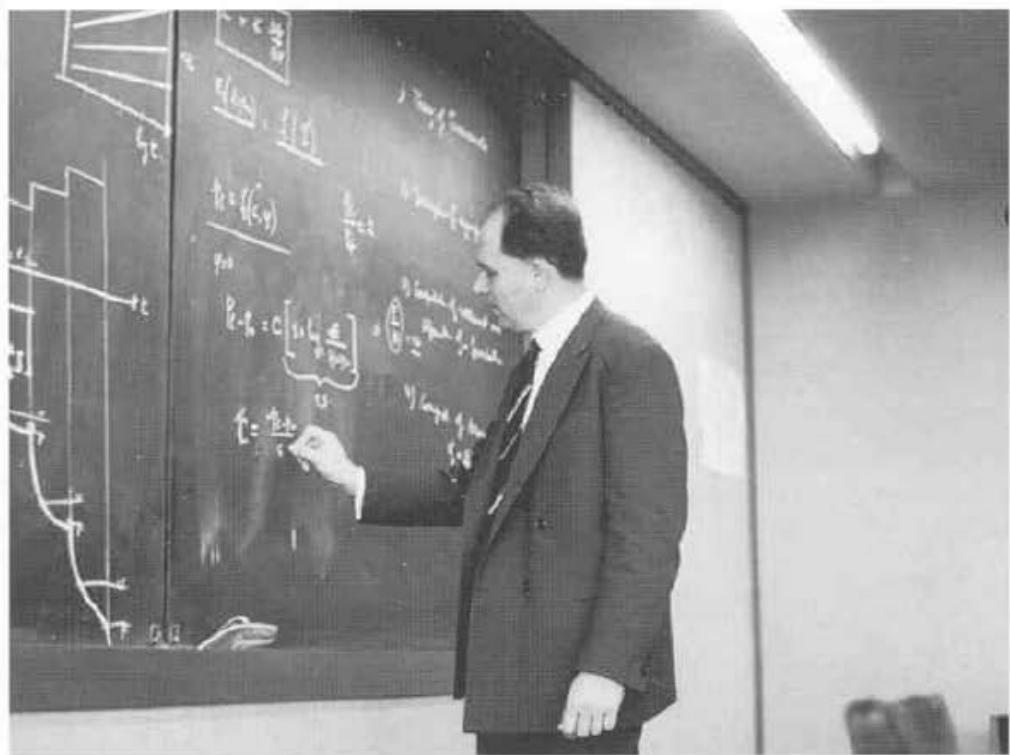

2.5 Prestigious applications

2.6 ARSCOP project

Louis MENARD (1933-1978)

ENGINEER, INNOVATOR

SOME HISTORY

- First pressuremeter idea:

1933 : first expansion test of cylindrical probe

1955 : patent by Louis Ménard and first instrument to measure
« pressure-time »
and
« pressure-deformation »
in cylindrical borehole

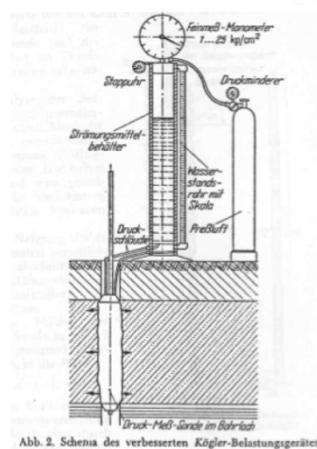

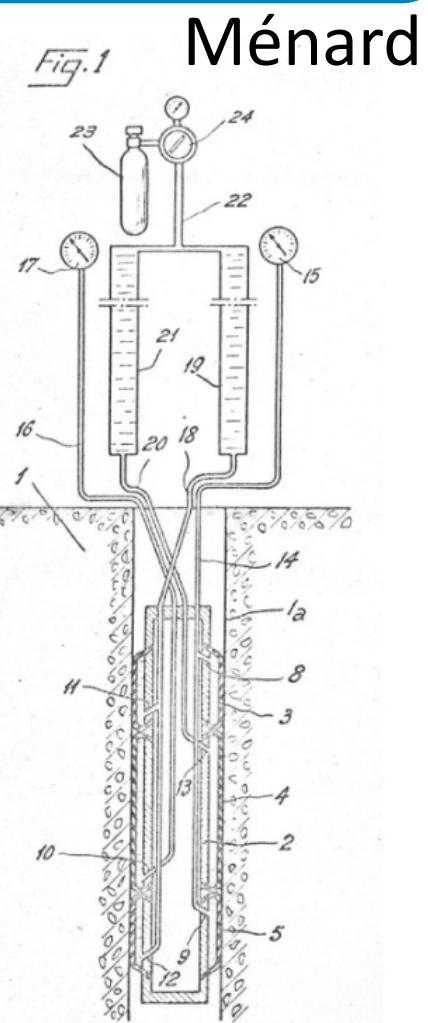

Abb. 2. Schema des verbesserten Kögler-Belastungsgerätes.

Germany
(not pursued)

Ménard pressuremeter

KEY DATES OF ORIGINS

Louis Ménard, civil engineer
and inventor of the pressuremeter

1955

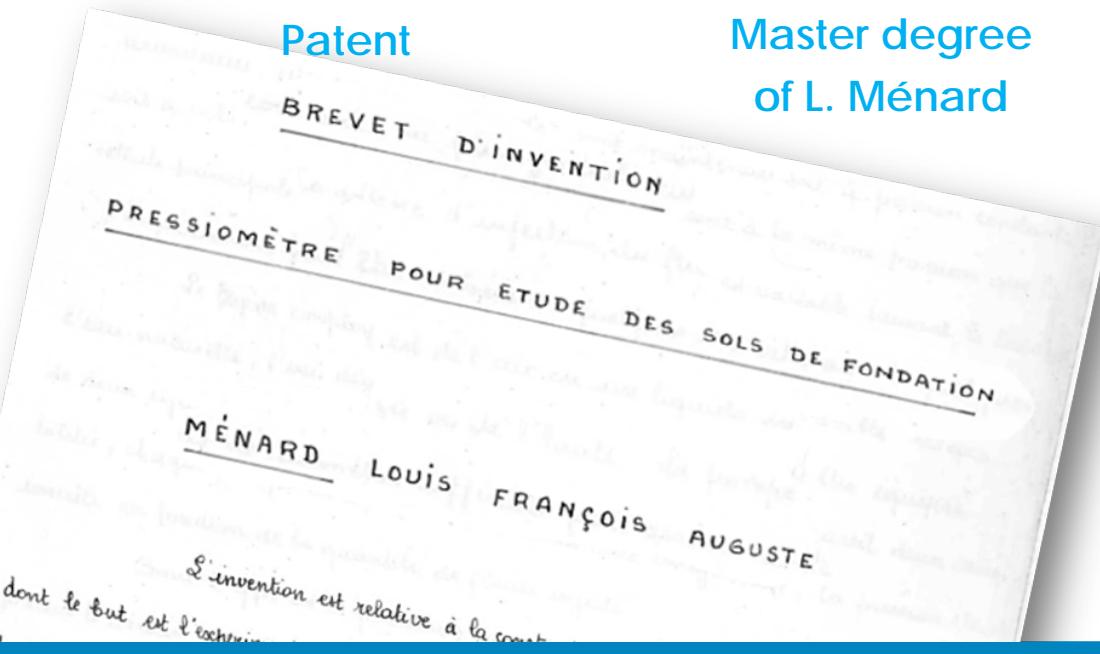

1956

1958

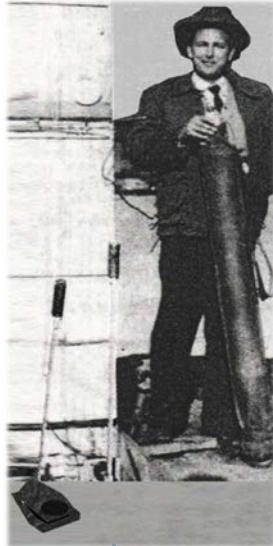

Patent

Master degree
of L. Ménard

First Company
Michel Gamin (Mike) joins

PRESSUREMETERS IMPROVEMENTS WITHIN THE FIRST DECADE

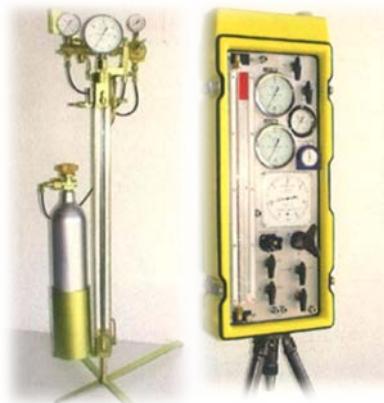

1955

The second PMT
prototype

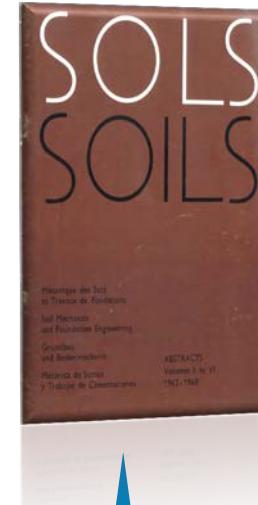

1967

D-9000
Versatile drill

1971-1975

G-type and
GC-type
Pressuremeter

1975

Soil-soils
edited by Mike Gambin

WHY PRESSUREMETER?

- Performed in previously drilled hole to any depth
- Performed in submerged sand or gravel, directly driven slotted casing or STAF® method
- Performed in fills even landfills (only possible technique)
- Provides its own reaction
- Large volume tested up to several tens of tons
- Average soil response
- Two stress-strain parameters
- Creep information
- Automatic data recording and test performance available
- Pressuremeter modulus (E_M) (independent from porepressure)
- Limit pressure (P_{LM}), close to failure of plate, footing or pile tip

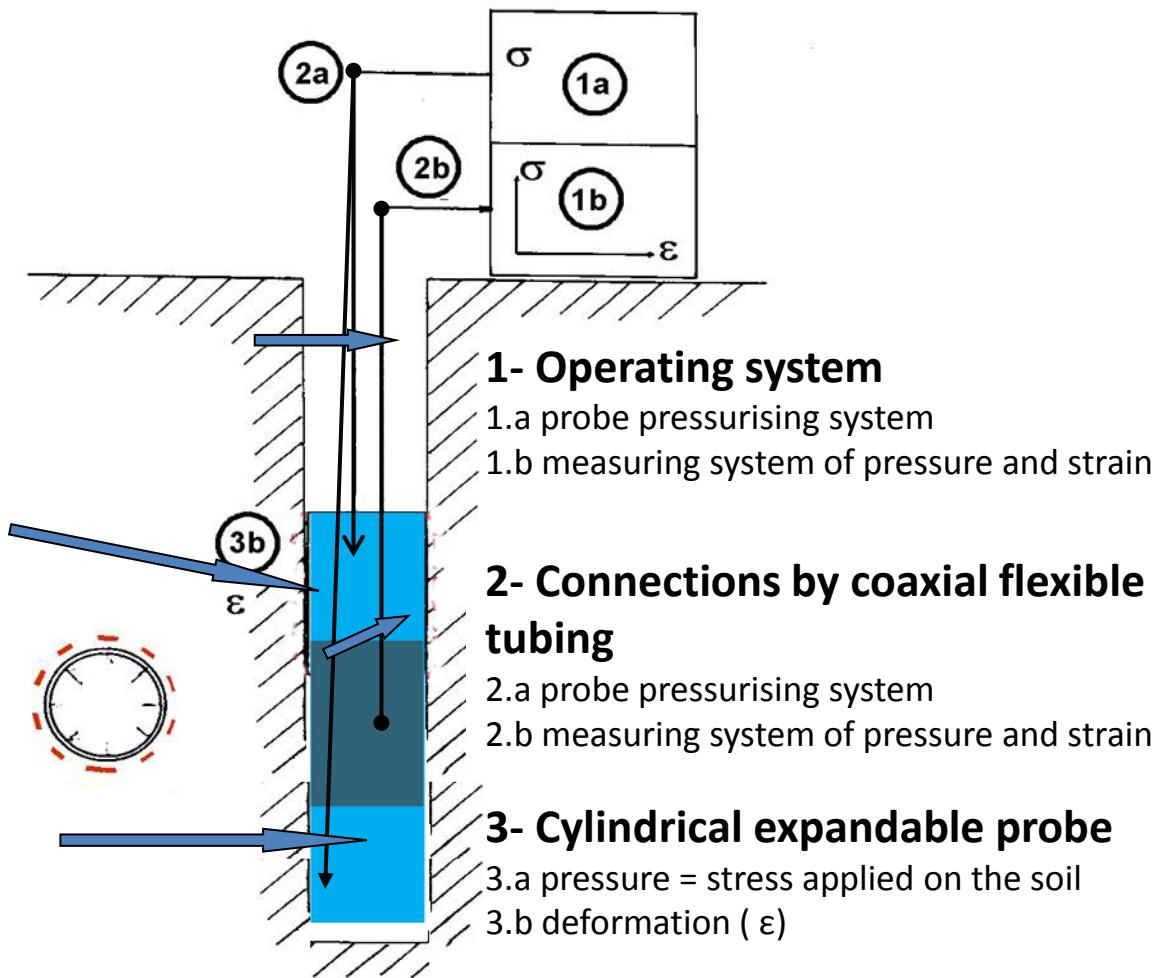

WHY STRESS CONTROLLED TESTS ?

- Strain is only consequence of stress and not its action
- Creep is available
- In construction, loading is stress controlled

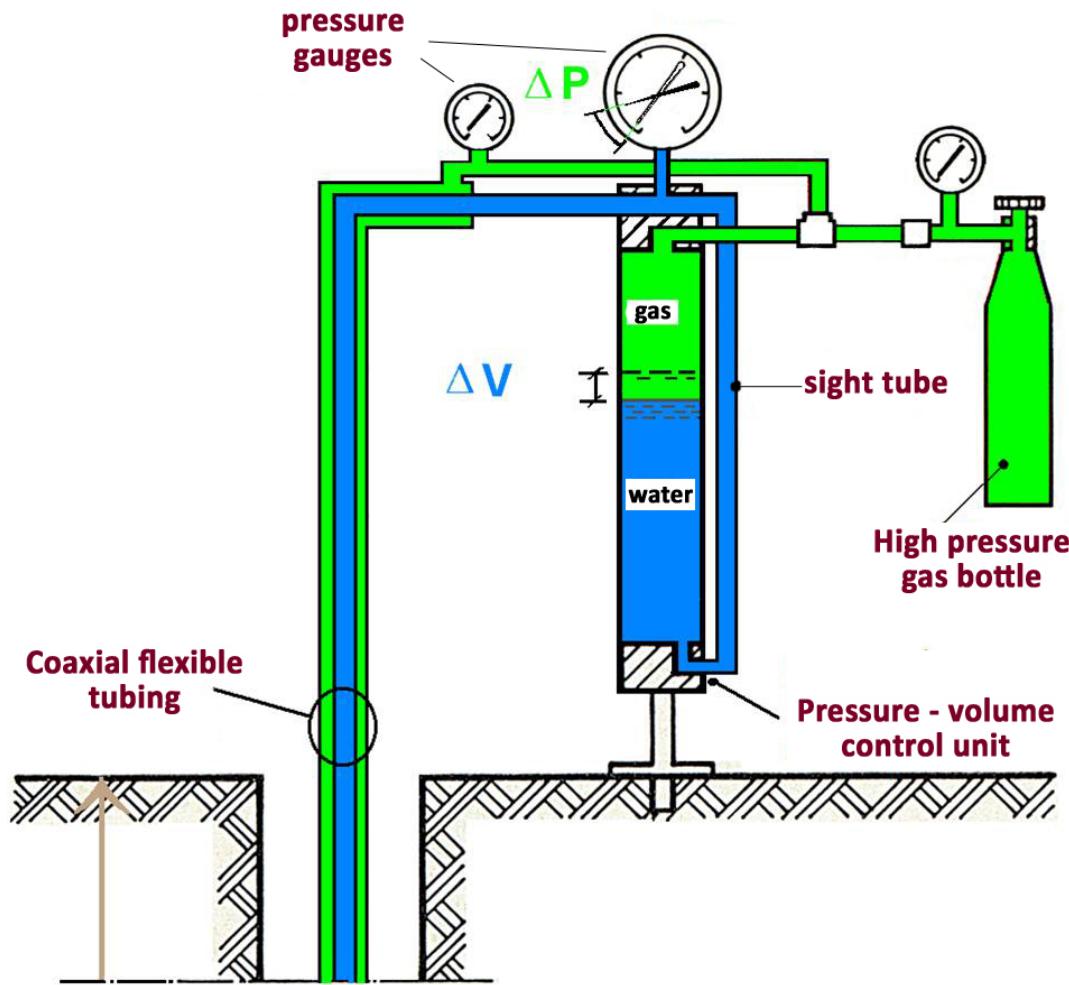

General principle of the pressuremeter

Cylindrical drilled hole

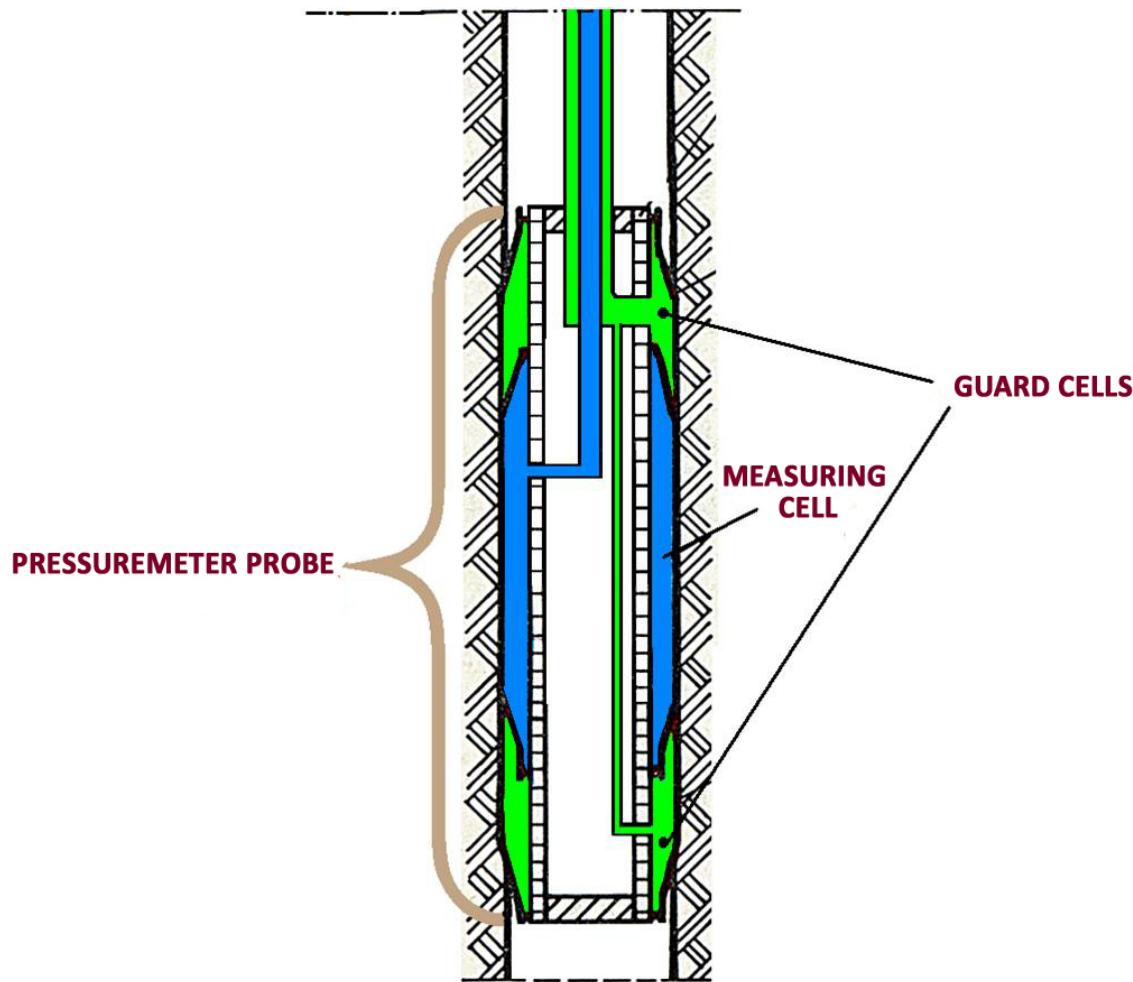

Objective :
measurement of radial expansion of the drilled hole by application of a cylindrical stress through an expandable cylindrical probe

General scheme of a Ménard pressuremeter

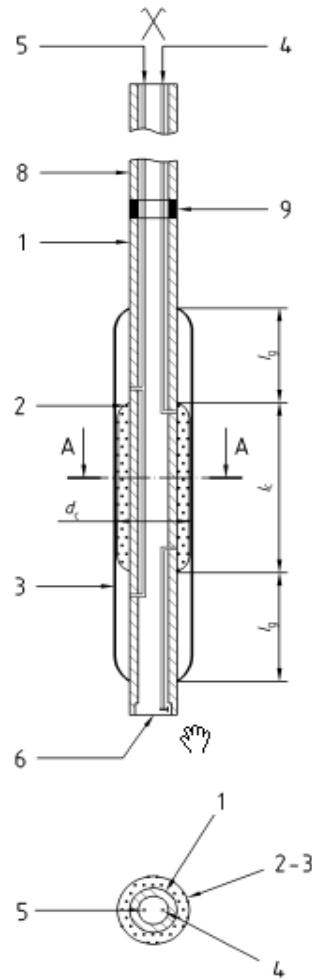

General scheme of a Ménard pressuremeter

Evolution of the pressuremeter

Detail of Ménard pressuremeter probe

Type G probe :

Central Cell + Flexible Cover to form 2 Guard Cells.

Central Cell Pressure is higher than in Guard Cells
to balance cell membrane resistance.

Pressure lag between the Central Cell and the
Guard Cells is kept constant at a given Depth

Latest state of the art

- GeoPAC® + GeoBOX
 - ⇒ High precision and high pressure measuring tool.
 - ⇒ Automatic piloting of the test, automatic recording and log presentation transmitted from GeoPAC® to GeoBOX® by Wifi and to the office by GPRS
 - ⇒ Stress-controlled test (possibilities of cyclic program)
 - ⇒ Ranges 0,1 cc to 100 Mpa

Evolution of drilling

- **Drilling methods from European norm**
 - Hand auger
 - Power auger
 - Rotary drilling bit with bentonite injection
 - Shelby tube sampler
 - Slotted casing driving method
 - Roto percussion
 - Open slotted casing
 - Recent STAF® Method (Self bored tube system)
 - Self-boring pressuremeter probe under development

Guidelines for pressuremeter probe placement techniques

*** Recommended

** Suited

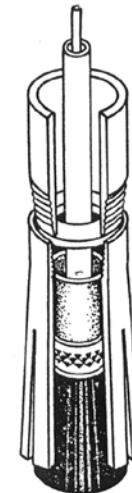

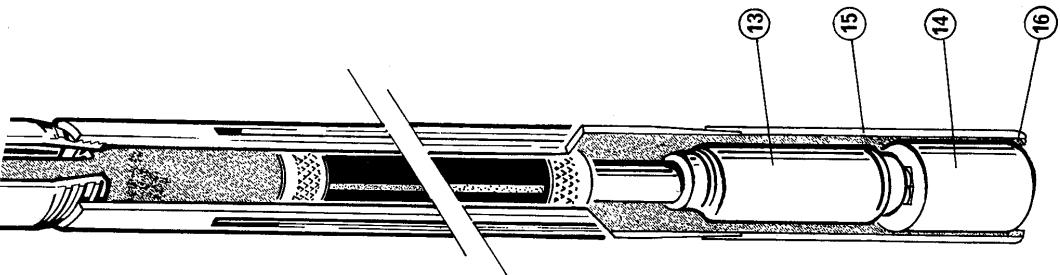

* Acceptable

- Not suited

Slotted casing method

(Fig. 3)

Cross
section of a
probe inside
a slotted
casing

The Menard Pressuremeter : typical loading tests

Typical **load tests** conducted on foundations :

- (i) PBT; and
 - (ii) PMT
- (not CPT or SPT)*

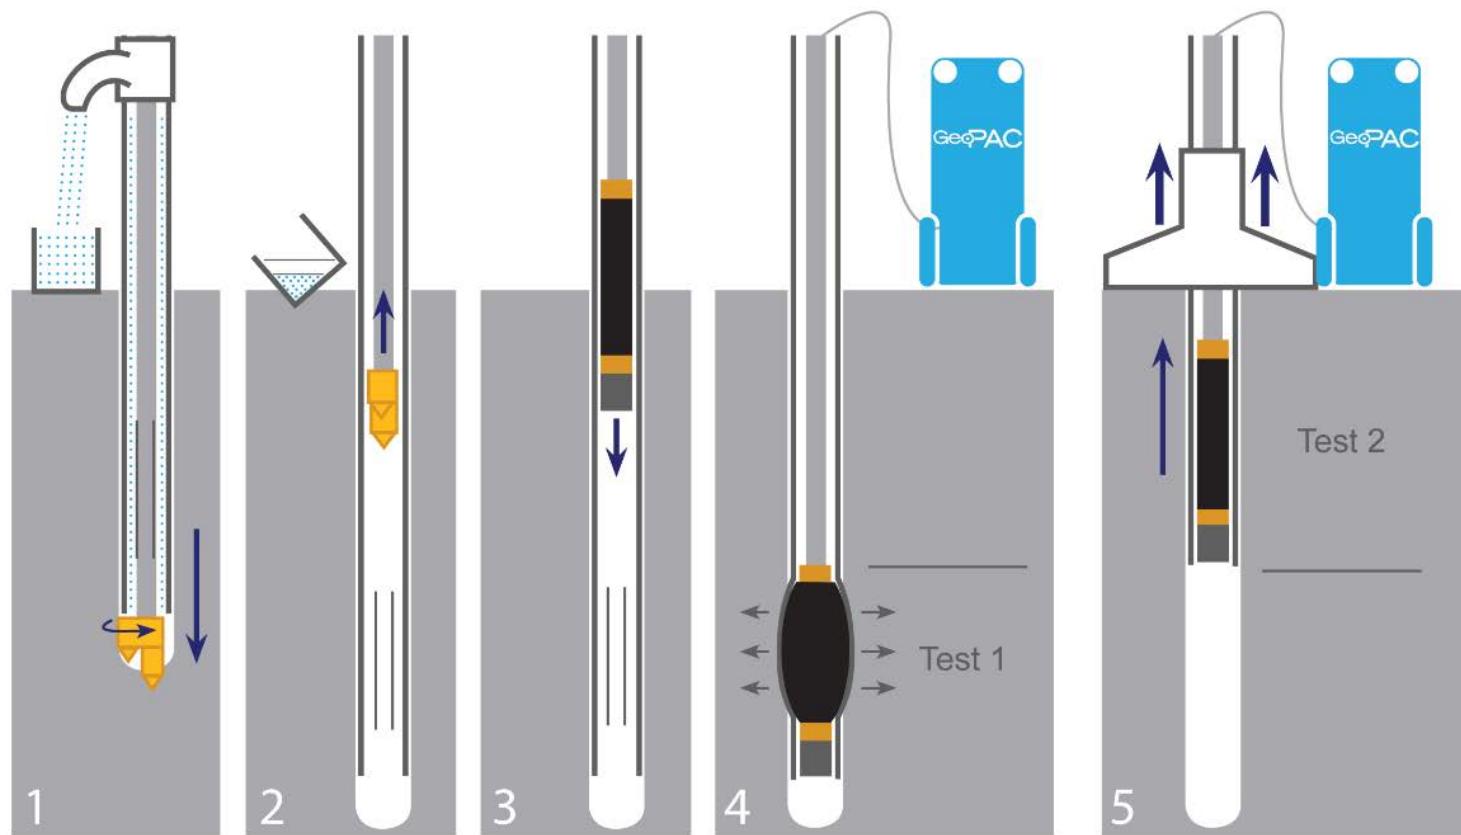

PBT – vertical load test

PMT – shear loading test

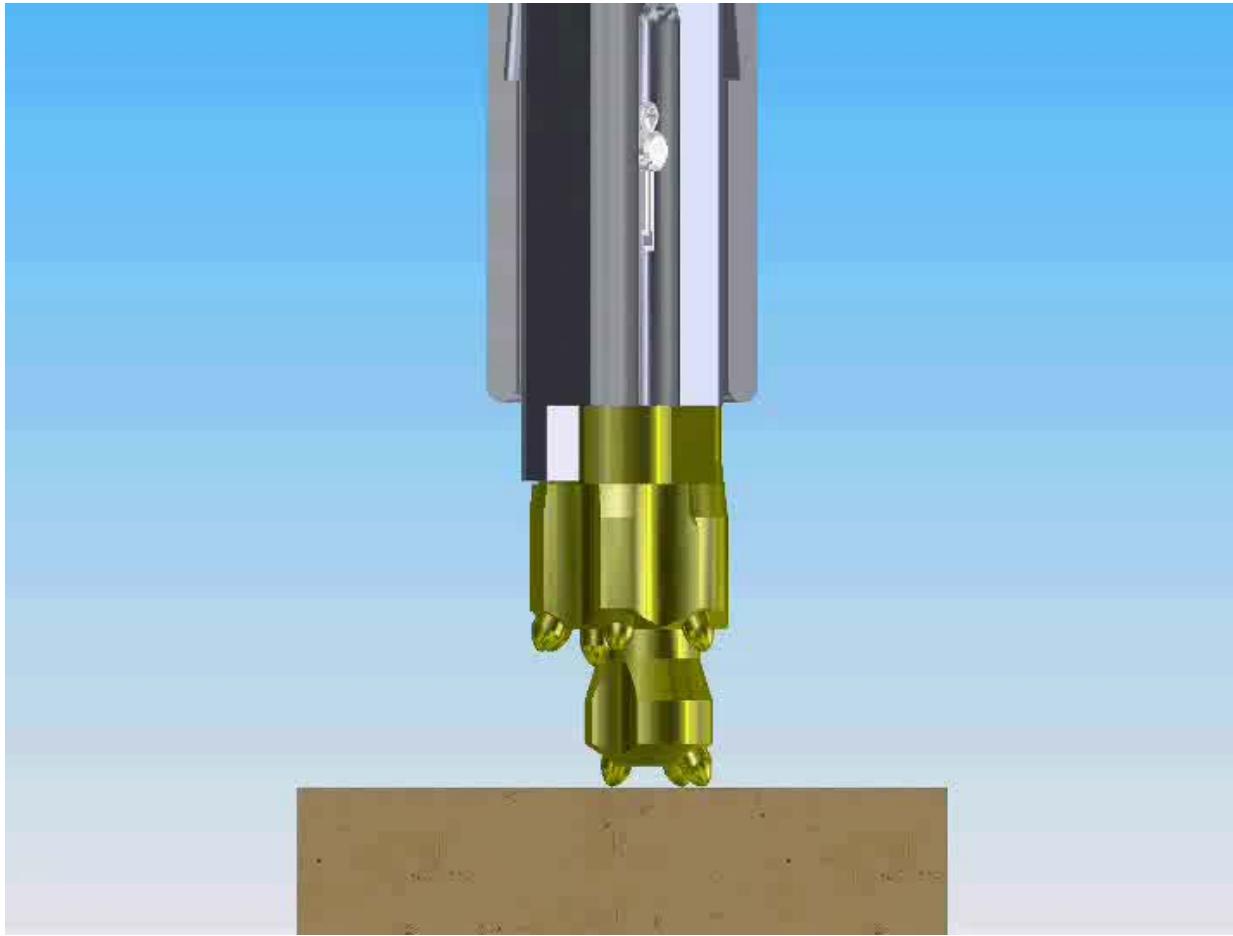

Self bored tube system STAF®

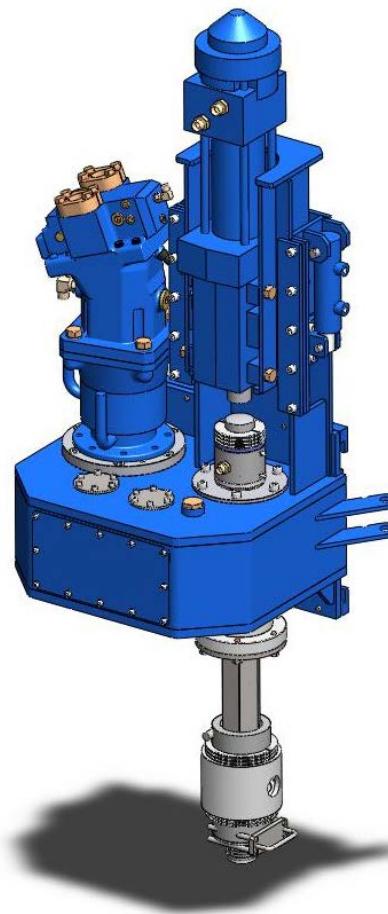

STAF® technique : Ménard Pressuremeter Tests inside a self-bored slotted tube

Self bored tube system STAF®

Roto percussion drilling to reduce casing friction

Research pressuremeter: PAF and K0 meter

Typical PMT test report and interpretation

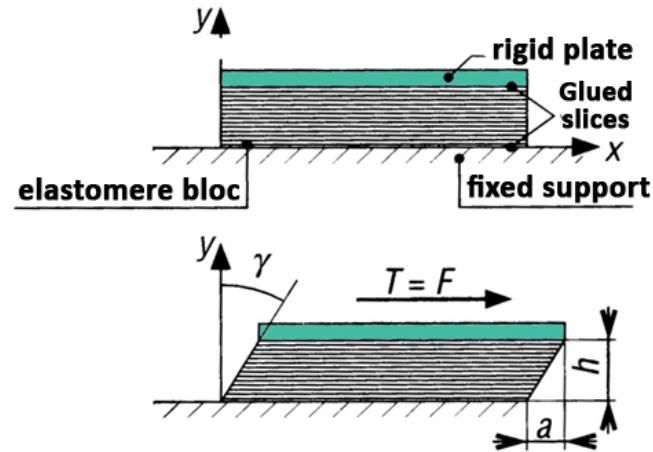

Various moduli deformation linear elastic case

Traction/compression

$$\varepsilon = d\ell / \ell$$

Shear angular deformation under shear

Young's modulus (not applicable in soils!)

$$\sigma = E \cdot \varepsilon$$

Shear modulus
Angular definition proportional to tangential stress

$$\tau = G \cdot \gamma$$

The expansion cylindrical cavity is an elastic medium according to Lamé :

$$G = V \cdot \frac{\Delta P}{\Delta V}$$

What is a pressuremeter modulus

- Compression modulus

$$E = \sigma / \varepsilon$$

- Shear modulus

$$G = \tau / \gamma$$

- Poisson coefficient (ν)

$$\nu = - \left(\frac{d\phi}{\phi} \right) / \left(\frac{d\ell}{\ell} \right)$$

- The relation between moduli is

$$E = 2(1 + \nu) \cdot G$$

- Ménard proposes to always adopt $\nu=1/3$

so

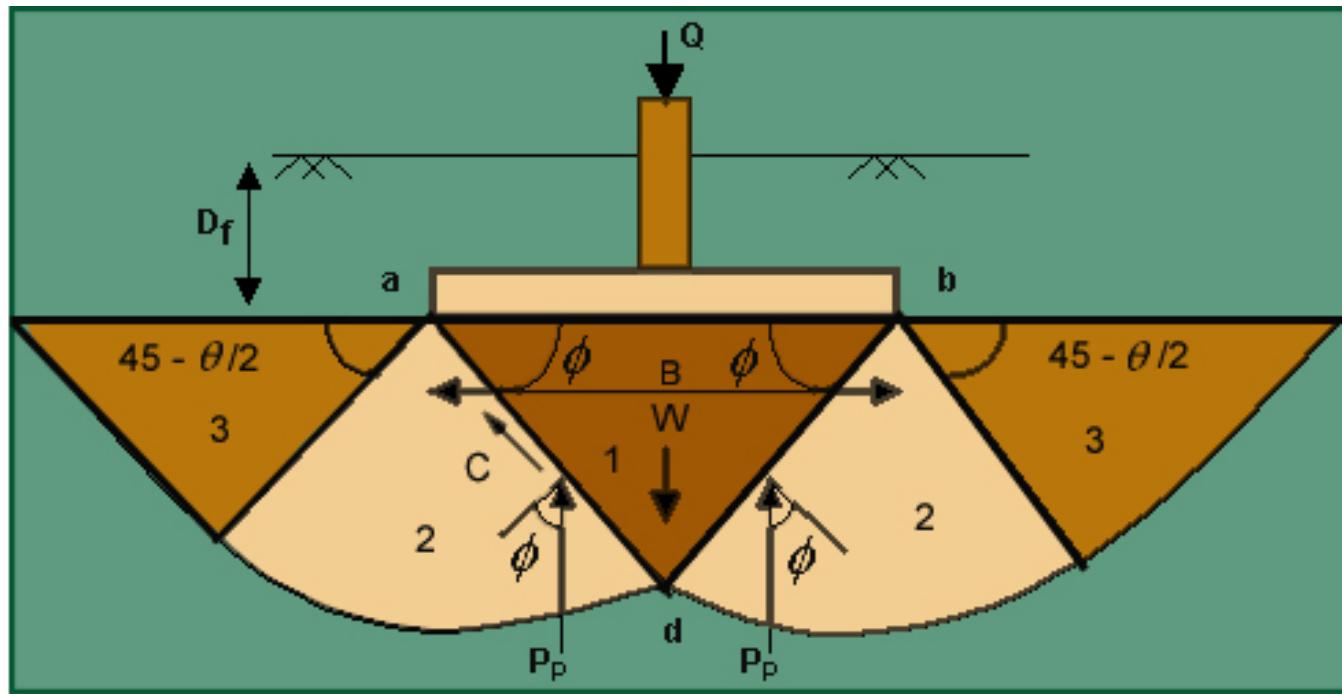

$$E_M = 2(1 + \nu) \cdot V_m \cdot \frac{\Delta P}{\Delta V}$$

or

$$E_M = \frac{8}{3} \cdot \left(V_s + \frac{V_1 + V_2}{2} \right) \cdot \frac{\Delta P}{\Delta V}$$

Bearing capacity

- Prandtl and Terzaghi theory and limitations

Prandtl's Theory on Bearing Capacity Analysis

Prandtl 1920 developed an equation based on his study of penetration of long hard metal puncher into softer materials for computing the ultimate bearing capacity. He made the following assumptions for the derivation.

- The material is softer, homogeneous and isotropic.
- The material is weightless and possesses only friction and cohesion.
- The problem is two dimensional
- The base of the puncher is smooth.
- The material behaves as a rigid body.
- The volume change will be Zero.
- The resulting deformation will be a plastic deformation.

Bearing capacity after Terzaghi
Function of (h , γ , D , c , Φ)

Bearing capacity after Ménard
Function of $q_L - q_o = k_p (p_{LM} - p_o)$

$$q_L - q_o = k_p (p_{LM} - p_o)$$

here q_L is the ultimate bearing stress at the footing or pile tip

- q_o the vertical overburden stress at pile tip depth

- k_p the Ménard Bearing Factor at footing or pile tip and type of soil

- p_{LM} the Ménard limit pressure at footing or pile tip depth

- p_o the insitu horizontal effective stress at footing or pile tip depth

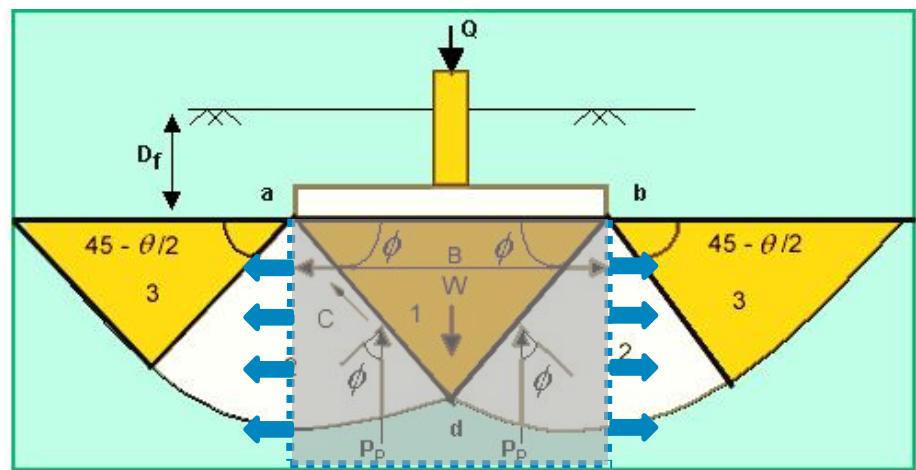

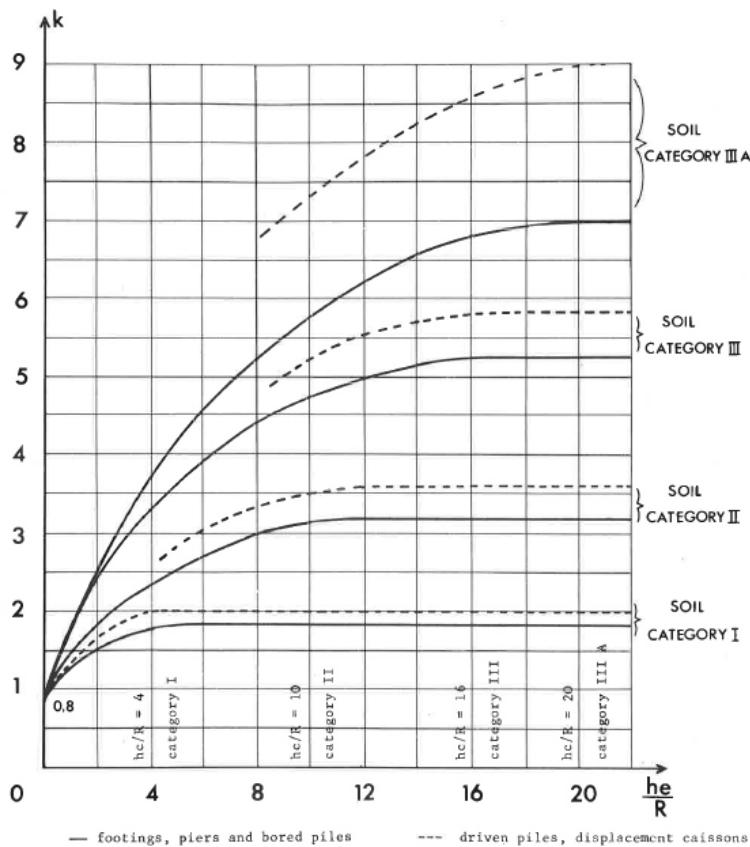

and it appears that, below a “critical depth”, the tip bearing capacity alone is much

less than predicted by the c' and Φ' (Mohr - Coulomb)

Pressuremeter bearing capacity factor

BEARING FACTOR AGAINST EMBEDMENT

FOR ISOLATED FOOTINGS, PIERS AND PILES

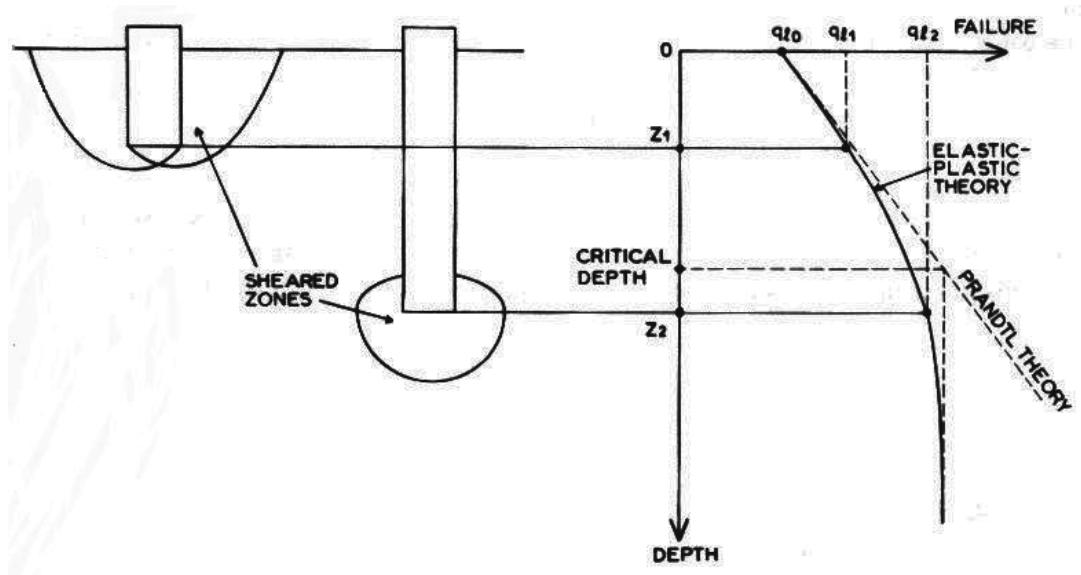

Pressuremeter probe, equal active zone
Surrounding soil passive reaction

Bearing capacity

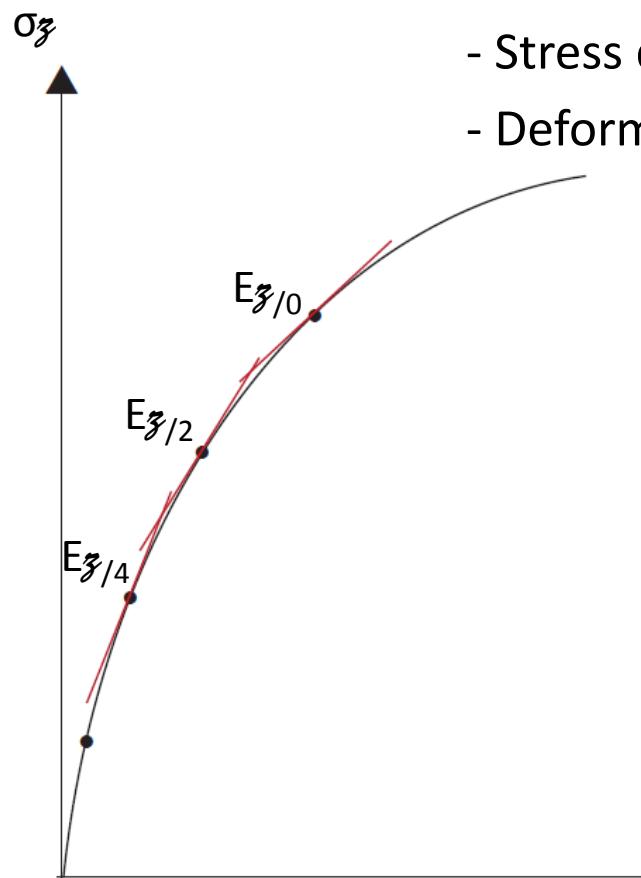

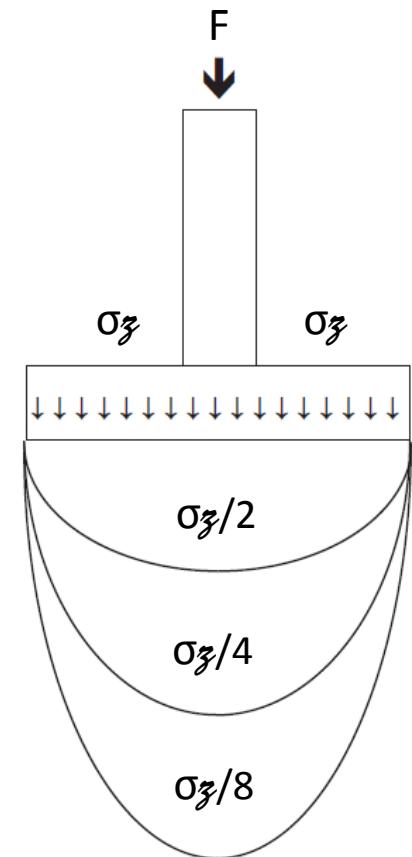

- Piles and drilling shafts

The soil response in a pressuremeter test behaves much closer to the way soil reacts to a loaded deep foundation a fact observed by many researchers. It is the estimate of the settlement, which provides the value of the bearing stress in service (Terzaghi & Peck, 1948), especially in sands, when deeper foundations are considered. The soil around the tip is in a plastic state and the soil reaction around this sheared volume can be compared with the response to the expansion of a deeply embedded cavity. Elastic/plastic theory must be used.

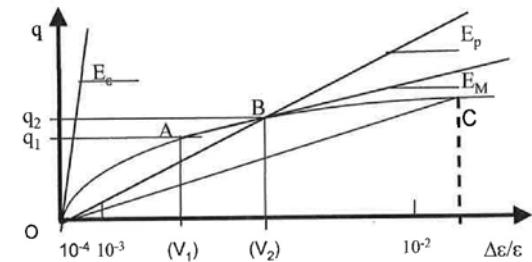

Shallow foundation bearing failure against pile tip bearing failure in an homogeneous soil (E_M & p_{LM} constant).

Why E_y young modulus

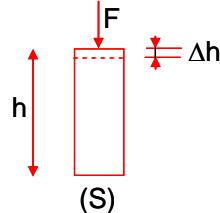

- E_z = variable not applicable for soils
- Be careful with FEM
- Stress distribution FEM is OK
- Deformation analysis FEM not correct

Duncan and Cheng

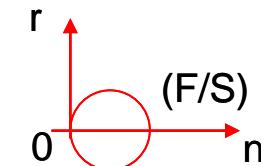

Settlement and deformation

A/ Simple compression

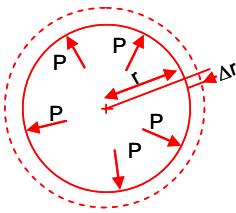

$$\frac{\Delta h}{h} = \frac{1}{E_{cs}} \frac{F}{S}$$

where E_{cs} is the compression

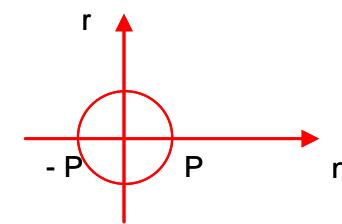

B/ Simple shear

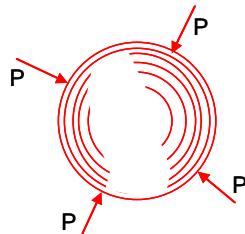

$$\frac{\Delta r}{r} = \frac{1 + \nu}{E_{pr}} p$$

where ν is the Poisson's coefficient

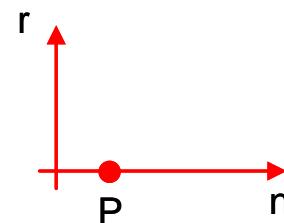

C/ Simple compression

$$\frac{\Delta r}{r} = \frac{1 - 2\nu}{E^+} p$$

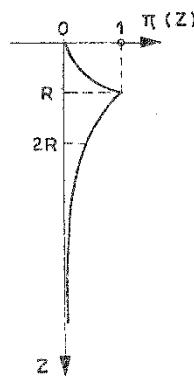

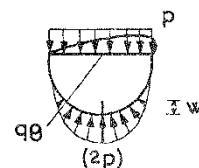

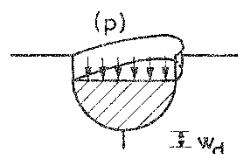

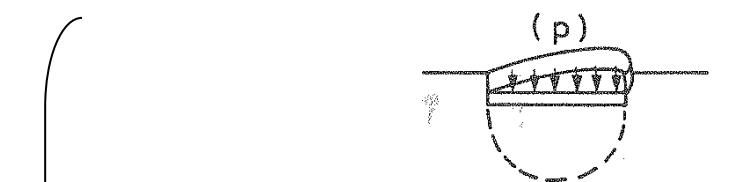

where E^+ is the hydrostatic compression modulus

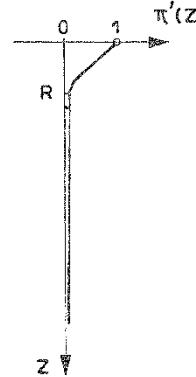

Settlement and deformation

D/ Menard deformation approach

$$W_{(10 \text{ years})} =$$

Shear domain

Spherical domain or volumetric

NO TENSION IN SOIL IMPACTS THE PMT MODULUS BECAUSE ELASTICITY ASSUMES TENSION

$$\varepsilon_r = \frac{\sigma_r}{E_r} - \nu_{\theta r} \frac{\sigma_\theta}{E_\theta} - \nu_{zr} \frac{\sigma_z}{E_z}$$

$$\varepsilon_\theta = -\nu_{r\theta} \frac{\sigma_r}{E_r} + \frac{\sigma_\theta}{E_\theta} - \nu_{z\theta} \frac{\sigma_z}{E_z}$$

ORTHOTROPIC
ELASTICITY

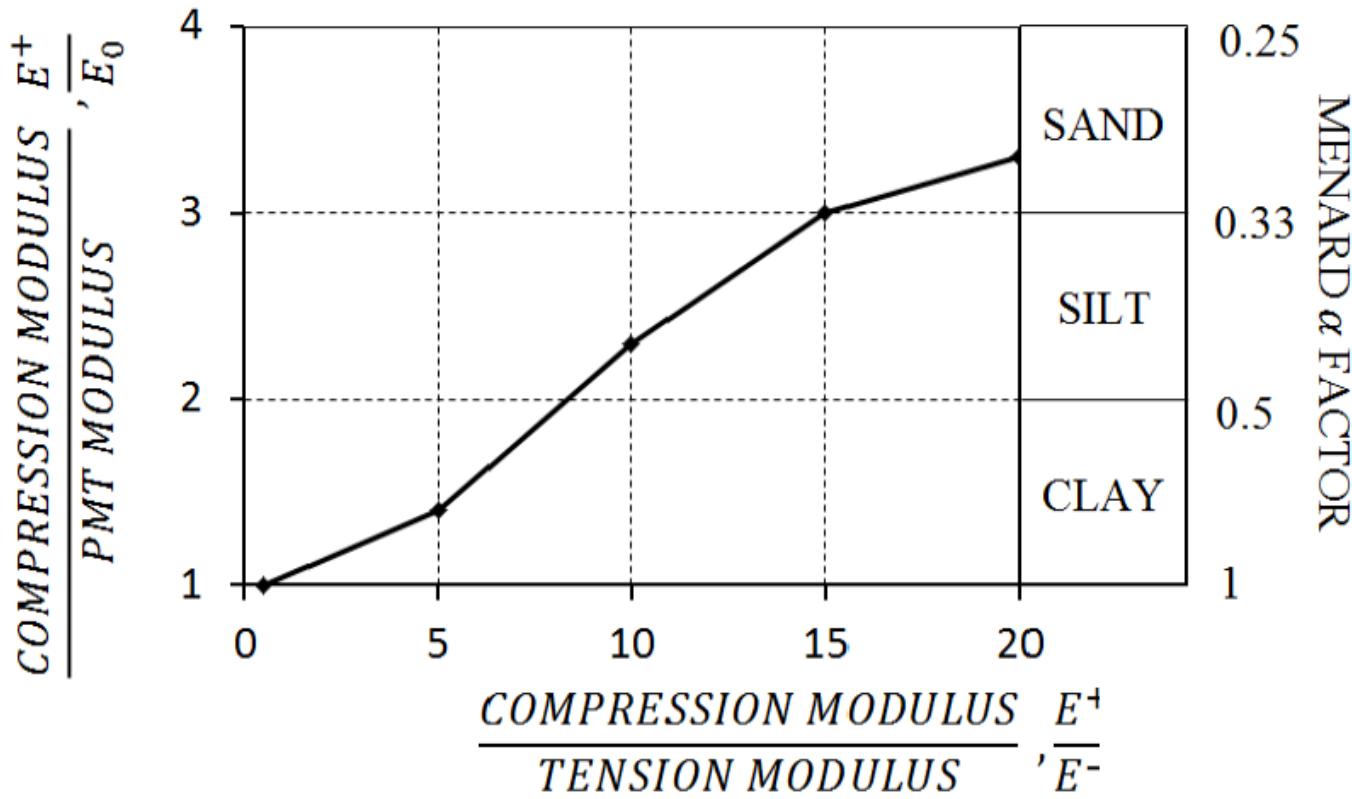

$$\varepsilon_z = -\nu_{rz} \frac{\sigma_r}{E_r} - \nu_{\theta z} \frac{\sigma_\theta}{E_\theta} + \frac{\sigma_z}{E_z}$$

$$E_z = E_r = E^+$$

$$E_\theta = E^-$$

Briaud, Ménard lecture 2013

NO TENSION IN SOIL IMPACTS THE PMT MODULUS BECAUSE ELASTICITY ASSUMES TENSION

Briaud, Ménard lecture 2013

Shape factor	λ _d	1,10
Shape factor	λ _s	1,12

$$W = \frac{1.33}{3E_d} p R_0 \left(\lambda_d \frac{R}{R_0} \right)^\alpha + \frac{\alpha}{4.5 E_s} p \lambda_s R$$

Results

Spherical strain	W _s	0,07 cm
Deviatoric strain	W _d	0,51 cm
Calculated settlement	W	0,58 cm

Ménard Rheological coefficient α

Type of material	Peat		Clay		Alluvium		Sand		Sand and gravel	
	E/p _L	α								
Over consolidated			>16	1	>14	2/3	>12	½	>10	1/3
Normaly consolidated		1	9 - 16	2/3	8 - 14	½	7 -12	1/3	6-10	1/4
Weather or altered			7 - 9	1/2		1/2		1/3		1/4

E = the pressuremeter modulus of the soil, assumed to be homogeneous

P = the mean contact stress added to soil by the rigid footing

R_O = a reference equal to 30 cm

α = The structure coefficient variable according to the nature of the soil and the ratio E/pL obtained from the pressuremeter, derived from the following table

Pile settlement prediction load transfer method

For the pile tip, the shear stress effect controls the settlement

$$\Delta R/R = [1/4G] \Delta p \quad (6)$$

Thus, the settlement z_p of a pile tip is simply given (Frank & Zhao 1982) by : $z_p = (B/\lambda p) q_p$ (7)

where B is the diameter of the pile

- q_p the pile tip pressure, with $q_p < q_L$, (Fig.2) and

- λp is a factor which varies from 4.8 EM in

5 times smaller above the $q_L / 2$ stress.

follows :

$$z_{si} = (B/\lambda s) q_{si} \quad (8)$$

where B is the diameter of the pile,

q_{si} the estimated shaft friction of the i th

element against the soil but limited by to a

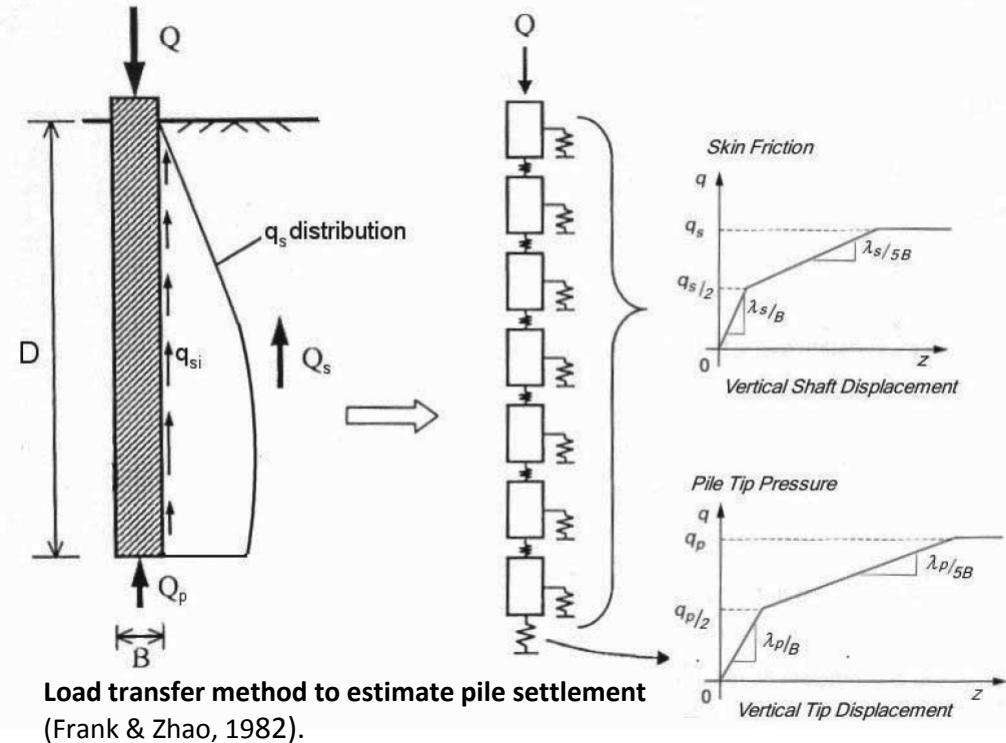

maximum of q_s as shown in Fig.2 – values are

given in Bustamante et al. (2009) and

- λs a factor which

- varies from 0.8 EM in coarse soils to 2 EM in fine soils up to a stress of $q_s / 2$

- and is 5 times smaller above the $q_s / 2$ stress.

Description and Characteristics of 418 loaded and analyzed piles

Group Code	Type No.	Pile ² Qty	B ³ (mm)	D ⁴ (m)	Pile Description
1	1	8	500-2,000	11.5-23	Pile or Barrette Bored in the dry
	2	64	270-1,800	6-78	Pile and Barrette Bored with Slurry

* If ground properties permit. ** Use of a higher value must be proven by a load test. *** Cross section and perimeter estimated according to Fig.3.

(a) For pile groups No.9 – 16 and if rock condition permits penetration, choose the q_s value proposed for marl and limestone or a higher one if this can be proven either by a load test or by reference to an existing example in the same local area.

Direct Design using PMT Data.

Chart for unit skin friction q_s

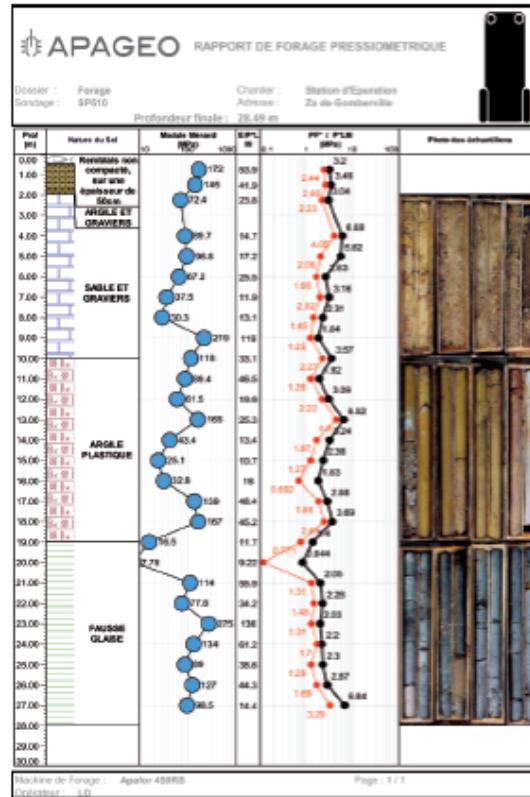

Software for geotechnical data

GEOVISION®
SOFTWARE
FOR GEOTECHNICAL DATA

THE +

- + Easy to use and intuitive interface
- + Personalized tables (diagraphy, graphs, reports)
- + Easy manual data input
- + Several work stations
- + Compatible with all the recent versions of Windows

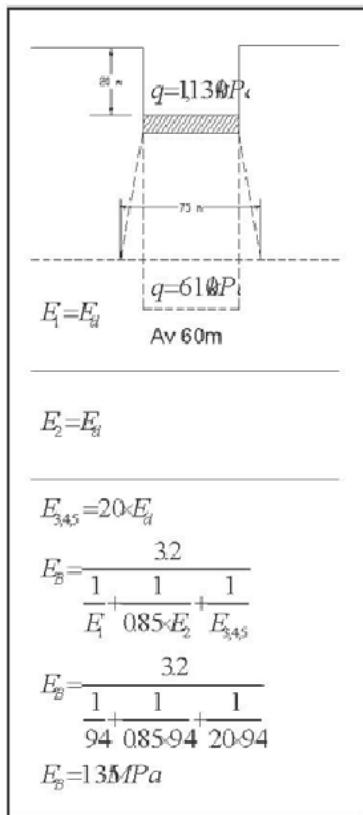

For each application, manual data input allows to complete data collected in soil.

GeoVISION® is a software that enables to extract, process and format of all data coming from APAGEO data loggers. Data is inserted through a USB device, memory stick, GPRS (option) or manual input. You can easily integrate notes, image or representative values of soil investigation.

SETTLEMENT UNDER HIGH RISE BUILDINGS IN CHICAGO

TERZAGHI LECTURE 2009

Clyde N. BAKER Jr

Pressuremeter Data

$$E_d = 94.3 MPa$$

$$E^+ = 267 MPa$$

$$\alpha = \frac{E_d}{E^+} = 0.35, \text{ Use } 0.4$$

Settlement Calculation – Menard Empirical Method

$$s_{Menard} = \frac{1.33}{3 \times E_B} q R_0 \left(\lambda_2 \frac{R}{R_0} \right)^{\alpha} + \frac{\alpha q \lambda_3 R}{4.5 E_1}$$

$\lambda_2, \lambda_3 = 1$ for a circle

$$R_0 = 30 cm$$

$$s_{Menard} = 0.55 cm + 2.16 cm = 27.1 mm$$

Settlement Calculation – Elastic Theory

$$s_{Elastic} = \frac{\mu_0 \mu_1 q B}{E}$$

$$s_{Elastic} = \frac{0.35 \times 0.92 \times 6,100 \times 75,000}{250,000} = 59 mm$$

Measured 24 mm

SETTLEMENT UNDER HIGH RISE BUILDINGS IN CHICAGO

TERZAGHI LECTURE 2009

Clyde N. BAKER Jr

Core Mat on 34 caissons	602,110	1,2 cm	1,2 cm
Isolated Caisson	52,490	1,9 to 2,5 cm	1,6 cm
NW Column on 3 Caissons	49,420	1,9 to 2,5 cm	1,6 cm
N Column on 3 Caissons	66,590	1,9 to 2,5 cm	2,0 cm

CONCLUSION OF SETTLEMENT '94

- Soil non homogeneity disappears when using PMTs
- The ratio Settlement w / foundation width B remains constant
- Settlement curves are superposed when w/B is reported to measured p_{LM}
- Settlement curves $w = f(q)$ can be predicted from PMTs results
- The Louis Ménard's bearing factor can be exactly derived from a simple analysis of the parameters of the loading test
- There is no size effect apparent in the settlement value of a square footing loaded up to the maximum safe load
- Then, the Terzaghi bearing capacity becomes questionable

FRENCH NATIONAL PROJECT ARSCOP

ARSCOP

A French national project to promote and foster geotechnical engineering based on pressuremeter

3 main objectives

- Consolidate and reinforce the French practice
- Continue with the development of the pressuremeter and its calculation methods
- Foster the pressuremeter outside France

WORK PACKAGES

Task 1: Develop testing devices and test procedures to increase reliability and performance of the test

Task 2: Develop calculation methods and calculation models from the use of pressuremeter by incorporating the latest advances made in the field of numerical modeling of geotechnical structures

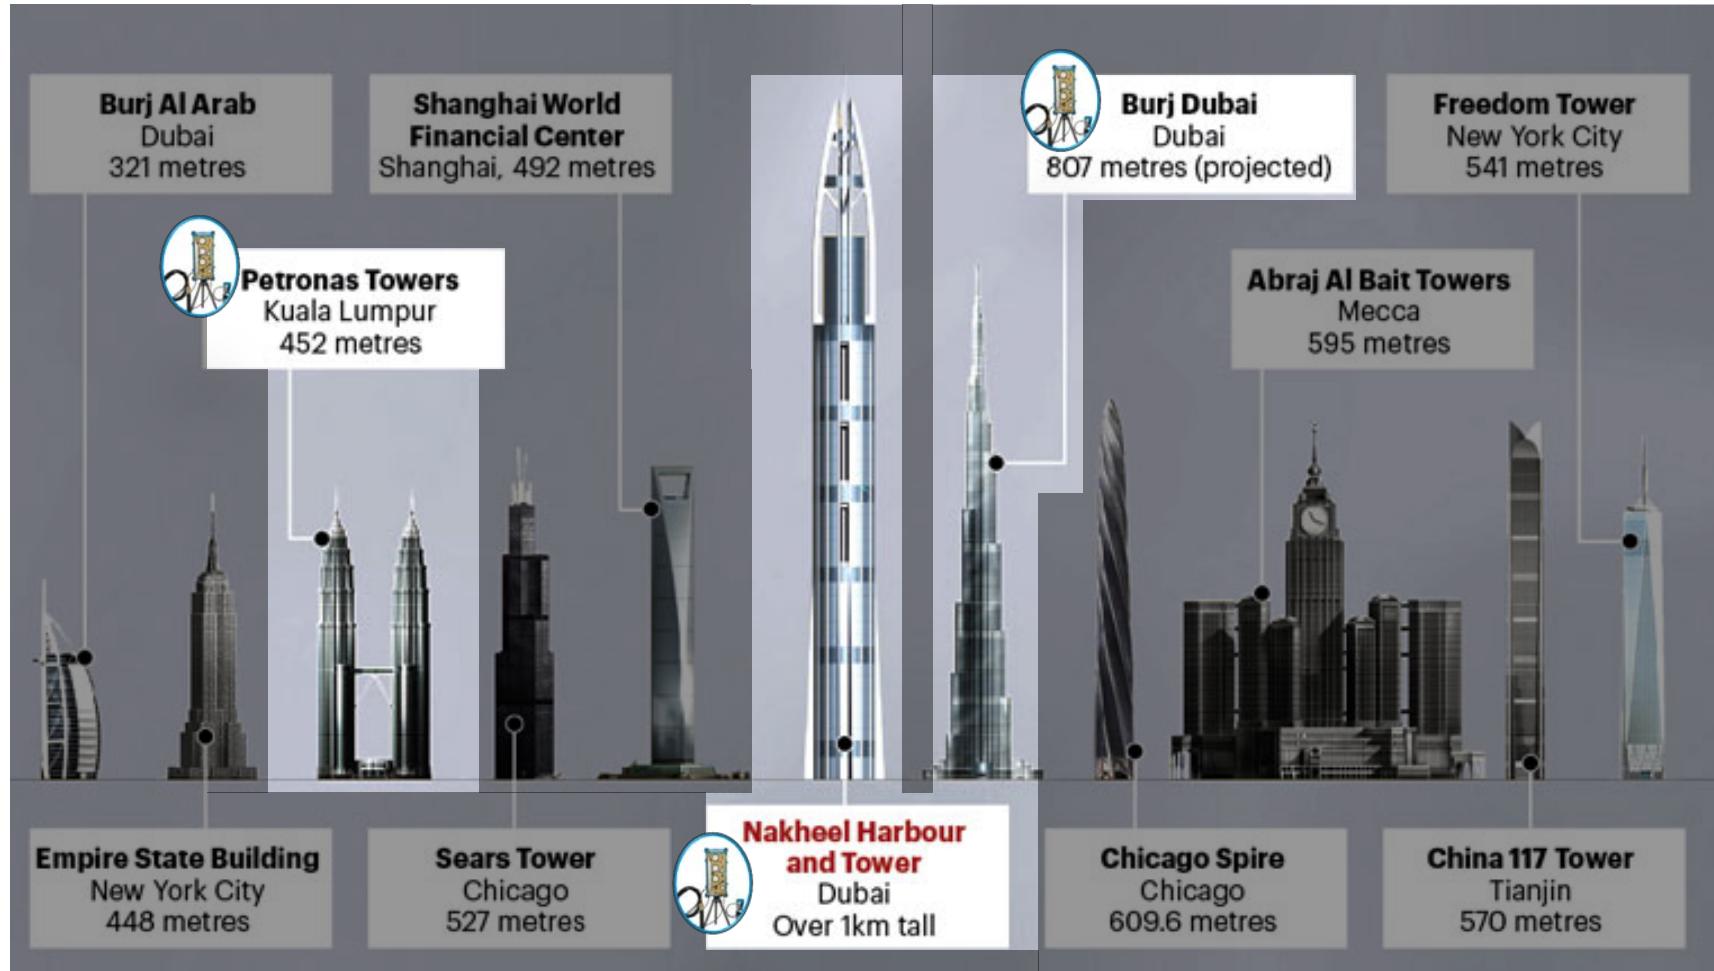

Task 3: Creation of database for calibration and validation of calculation methods using results obtained from pressuremeter tests
